The purpose of temperature of fever

Yacob Mathai

Marma Health Centre, India

When the disease becomes threat to life or organs blood circulation decreases, temperature of fever will emerge to increase prevailing blood circulation and it acts as a protective covering of the body to sustain life. When blood flow decreases to brain, the patient becomes fainted or delirious. If we try to decrease temperature of fever, the blood circulation will further get reduced. Blood circulation never increases without temperature increase. Delirious can never be cured without increase in blood circulation. The temperature of fever is not a surplus temperature, or it is not to be eliminated from the body. During fever, our body temperature increases like a brooding hen's body temperature. The actual treatment of fever is to increase blood circulation. There are two ways to increase blood circulation: (1) Never allow body temperature to lose; (2) Apply heat from outside to the body. When the temperature produced by body due to fever and heat which we applied on the body combines, the blood circulation increases. Then body will stop producing heat to increase blood circulation. And body will get extra heat from outside without any usage of energy. How can we prove that the temperature of fever is to increase blood circulation? If we ask any type of question related to fever by assuming that the temperature of fever is to increase blood circulation, we will get a clear answer. If avoid or evade from this definition, we will never get proper answer to even a single question. If we do any type of treatment by assuming that the temperature of fever is to increase blood circulation, the body will accept, at the same time body will resist whatever treatment to decrease blood circulation. No further evidence is required to prove the temperature of fever is to increase blood circulation.
